

### CO342 ASSIGNMENT #6 SOLUTIONS

1. In the figure is an example of a graph  $G$ . The set of coloured edges represent three pairwise edge-disjoint  $av$ -paths in  $G$ . Illustrate the labelling algorithm and use it to produce a largest possible set of pairwise edge-disjoint  $av$ -paths in  $G$ .

An augmenting path for the original collection is in purple.

The resulting larger collection of edge-disjoint paths.

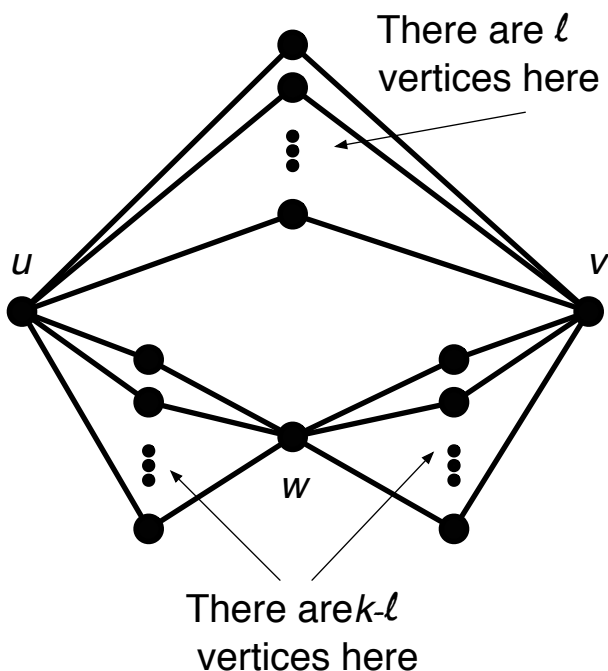

An augmenting path for the new collection is  $u, g, n, h, k, p, t, v$  (using the red edge  $nh$ ) yielding the still larger collection.

The labelled vertices at the end of the labelling algorithm yields the 5-cut shown in dashed edges, one of each of the five non-black colours.

2. For each pair of positive integers  $k$  and  $\ell$ , with  $k > \ell$ , give an example of a graph  $G$  having a pair of vertices  $u$  and  $v$  so that:
- a largest set of pairwise edge-disjoint  $uv$ -paths in  $G$  has size  $k$ ; and
  - there is a vertex  $w$  of  $G$ , different from  $u$  and  $v$ , so that the largest set of pairwise edge-disjoint  $uv$ -paths in  $G - w$  has size  $\ell$ .

3. Let  $u$ ,  $v$ , and  $w$  be distinct vertices in a graph  $G$ . Suppose there are  $k$  pairwise edge-disjoint  $uv$ -paths in  $G$  and there are  $k$  pairwise edge-disjoint  $vw$ -paths in  $G$ . Prove that there are  $k$  pairwise edge-disjoint  $uw$ -paths in  $G$ .

**SOLUTION.** Let  $E$  be a smallest set of edges so that  $u$  and  $w$  are in different components of  $G - E$ . Let  $K_u$  be the component of  $G - E$  containing  $u$  and let  $K_w$  be the component of  $G - E$  containing  $w$ .

If  $v$  is in  $K_u$ , then  $E$  is a set of edges so that  $v$  and  $w$  are in different components of  $G - E$ . Since there are  $k$  pairwise edge-disjoint  $vw$ -paths

in  $G$ ,  $|E| \geq k$ , as required. A very similar argument applies if  $v$  is not in  $K_u$ .

4. In this exercise, we shall deduce the edge-disjoint version of Menger's Theorem from the internally disjoint version.

**Internally-disjoint Menger's Theorem:** For non-adjacent vertices  $u$  and  $v$  of  $G$ , let  $\kappa_G(u, v)$  denote the size of a smallest  $uv$ -cut. Then there is a set  $\mathcal{P}$  of pairwise internally-disjoint  $uv$ -paths in  $G$  so that  $|\mathcal{P}| = \kappa_G(u, v)$ .

**Edge disjoint version of Menger's Theorem:** let  $u$  and  $v$  be vertices in a graph  $G$ . Then the maximum size of a set of pairwise edge-disjoint  $uv$ -paths in  $G$  is equal to the minimum size of a set  $F$  of edges of  $G$  so that  $G - F$  has no  $uv$ -path.

**SOLUTION.** Create a new graph  $G'$  as follows:

- the vertex set of  $G'$  is  $u, v$ , and, for each edge  $e$  of  $G$ , a vertex  $w_e$ ;
- for each edge  $e$  of  $G$  incident with  $u$ , there is an edge  $uw_e$  in  $G'$ ;
- for each edge  $e$  of  $G$  incident with  $v$ , there is an edge  $vw_e$  in  $G'$ ;
- if  $e$  and  $e'$  are edges of  $G$  both incident with the vertex  $x$  of  $G$ ,  $x \neq u, v$ , then  $w_e$  and  $w_{e'}$  are adjacent in  $G'$ .

We apply the internally-disjoint version of Menger's Theorem to  $G'$ , obtaining a set  $\mathcal{P}'$  of internally-disjoint  $uv$ -paths in  $G'$  and a set  $W'$  of vertices in  $G'$  so that: (a)  $u$  and  $v$  are in different components of  $G' - W'$ ; and (b)  $|\mathcal{P}'| = |W'|$ .

With one small technical point, we claim that each  $uv$ -path in  $G'$  produces a  $uv$ -path in  $G$ . Let  $(w_0, w_1, w_2, \dots, w_k)$  be a  $uv$ -path  $P'$  in  $G'$ , so  $w_0 = u$  and  $w_k = v$ . There may be an edge, called a chord,  $w_i w_j$  in  $G$ , with  $j \geq i+2$ , and we could get the shorter path  $(w_0, w_1, \dots, w_i, w_j, w_{j+1}, \dots, w_k)$ . Repeat as long as there is a chord of the current path. Let  $P'^* = (v_0, v_1, v_2, \dots, v_\ell)$  be the resulting path.

The path  $P'^*$  corresponds to a path in  $G$ : start at  $u$ , and proceed successively along the edges  $v_1, v_2, \dots, v_\ell$  of  $G$ . Since each  $v_{i-1}$  is joined by an edge in  $G'$  to  $v_i$ , this implies that  $v_{i-1}$  and  $v_i$  have a common end

$u_i$  in  $G$ . (The argument is slightly different if  $i = 1$ , so  $v_{i-1} = u$ , or  $i = \ell$ , so  $v_\ell = v$ , but you should see the point.)

We note that, by choosing  $P'^*$ , no other  $v_j$  can also be incident in  $G$  with  $u_i$ , since this implies either  $j < i - 1$  and  $v_j v_i$  is an edge of  $G'$  or  $j > i$  and  $v_{i-1} v_j$  is an edge of  $G'$ . In either case,  $P'^*$  has a chord, a contradiction. Therefore,  $(u, u_1, u_2, \dots, u_{k-1}, v)$  is a  $uv$ -path  $P$  in  $G$ .

Thus, each path  $P'$  in  $\mathcal{P}'$ , which we may take to be chordless, produces a path  $P$  in  $G$ . An edge of  $P$  corresponds to an internal vertex of  $P'$ . Since the paths in  $\mathcal{P}'$  are pairwise internally-disjoint, the paths  $P$  are pairwise edge-disjoint.

Also, each vertex of  $G'$  in  $W'$  corresponds to an edge of  $G$ ; let  $E$  be the set of such edges. If there were a  $uv$ -path  $Q$  in  $G - E$ , then, by following the edges of  $Q$ , we obtain a  $uv$ -path  $Q'$  in  $G' - W'$ . Since there is no such path, we conclude that there is no  $uv$ -path in  $G - E$ . Since  $\{P : P' \in \mathcal{P}'\}$  has the same size as  $\mathcal{P}'$ , and therefore as  $W'$ , and therefore, as  $E$ , we see that this is the edge disjoint version of Menger's Theorem.
